Inputs

The inputs were: $A = 5, B = 2, C = 18, D = 14$

The output was: 12

Description

I have created a web application that can read in four inputs from the url and do a simple equation with them. The main goal of this test has been achieved and as long as the inputs are all integers the code will run without error. However I wasn't able to add error checking as I ran out of time. To achieve this I created a new java class that does the mathematics and I also had to edit web.xml to add another servlet. I also had to edit the index.html file to include the url-address to the java class CloudPrint.
